0.2 Lexical

The lexical analysis is independent of the syntax parsing and the semantic analysis. The lexical analyzer splits the source text up into tokens. The lexical grammar describes what those tokens are. The grammar is designed to be suitable for high speed scanning, it has a minimum of special case rules, there is only one phase of translation, and to make it easy to write a correct scanner for. The tokens are readily recognizable by those familiar with C and C++.

0.2.1 Source Text

D source text can be in one of the following formats:

- ASCII
- UTF-8
- UTF-16BE
- UTF-16LE
- UTF-32BE
- UTF-32LE

UTF-8 is a superset of traditional 7-bit ASCII. One of the following UTF BOMs (Byte Order Marks) can be present at the beginning of the source text:

Format	BOM
UTF-8	EF BB BF
UTF-16BE	FE FF
UTF-16LE	FF FE
UTF-32BE	$00~00~\mathrm{FE}~\mathrm{FF}$
UTF-32LE	$\mathrm{FF}\;\mathrm{FE}\;00\;00$
ASCII	no BOM

If the source file does not start with a BOM, then the first character must be less than or equal to U0000007F.

There are no digraphs or trigraphs in D.

The source text is decoded from its source representation into Unicode Characters. The Characters are further divided into: WhiteSpace, EndOfLine, Comments, SpecialTokenSequences, Tokens, all followed by EndOfFile.

The source text is split into tokens using the maximal munch technique, i.e., the lexical analyzer tries to make the longest token it can. For example >> is a right shift token, not two greater than tokens. An exception to this rule is that a .. embedded inside what looks like two floating point literals, as in 1..2, is interpreted as if the .. was separated by a space from the first integer.

0.2.2 Character Set

Character:

any Unicode character

0.2.3 End of File

```
EndOfFile:

physical end of the file
\u00000
\u001A
```

The source text is terminated by whichever comes first.

0.2.4 End of Line

```
EndOfLine:
\u000D
\u000A
\u000D \u000A
\u2028
\u2029
EndOfFile
```

There is no backslash line splicing, nor are there any limits on the length of a line.

0.2.5 White Space

```
WhiteSpace:
Space
```

Space WhiteSpace

```
Space:
   110020
   \u0009
   \u000B
   \11000C
```

0.2.6 Comments

```
Comment:
   BlockComment
   LineComment
   NestingBlockComment
BlockComment:
   /* Characters */
LineComment:
   // Characters EndOfLine
NestingBlockComment:
   /+ NestingBlockCommentCharacters +/
```

NestingBlockCommentCharacters:

NestingBlockCommentCharacter
NestingBlockCommentCharacter NestingBlock(

NestingBlockCommentCharacter:

Character
NestingBlockComment

Characters:

Character
Character Characters

D has three kinds of comments:

- 1. Block comments can span multiple lines, but do not nest.
- 2. Line comments terminate at the end of the line.
- 3. Nesting block comments can span multiple lines and can nest.

The contents of strings and comments are not tokenized. Consequently, comment openings occurring within a string do not begin a comment, and string delimiters within a comment do not affect the recognition of comment closings and nested "/+"

comment openings. With the exception of "/+" occurring within a "/+" comment, comment openings within a comment are ignored.

```
a = /+ // +/ 1; // parses as if 'a = 1;' 
 a = /+ "+/"_{\sqcup} +/_{\sqcup} 1"; // parses as if 'a = " +/ 1" 
 a = /+ /* +/ */ 3; // parses as if 'a = */ 3;'
```

Comments cannot be used as token concatenators, for example, abc/**/def is two tokens, abc and def, not one abcdef token.

0.2.7 Tokens

```
Token:

```

0.2.8 Identifiers

Identifier:

IdentifierStart
IdentifierStart IdentifierChars

IdentifierChars:

IdentifierChar
IdentifierChars

IdentifierStart:

-Letter UniversalAlpha

IdentifierChar:

IdentifierStart O NonZeroDigit Identifiers start with a letter, _, or universal alpha, and are followed by any number of letters, _, digits, or universal alphas. Universal alphas are as defined in ISO/IEC 9899:1999(E) Appendix D. (This is the C99 Standard.) Identifiers can be arbitrarily long, and are case sensitive. Identifiers starting with __ (two underscores) are reserved.

0.2.9 String Literals

```

StringPostfix:

C

A string literal is either a double quoted string, a wysiwyg quoted string, an escape sequence, a delimited string, a token string, or a hex string.

In all string literal forms, an EndOfLine is regarded as a single \n character.

Wysiwyg Strings

Wysiwyg "what you see is what you get" quoted strings are enclosed by r" and ". All characters between the r" and " are part of the string. There are no escape sequences inside r" ":

```
r"hello"
```

An alternate form of wysiwyg strings are enclosed by backquotes, the 'character. The 'character is not available on some keyboards and the font rendering of it is sometimes indistinguishable from the regular 'character. Since, however, the 'is rarely used, it is useful to delineate strings with "in them.

Double Quoted Strings

Double quoted strings are enclosed by "". Escape sequences can be embedded into them with the typical \ notation.

Hex Strings

Hex strings allow string literals to be created using hex data. The hex data need not form valid UTF characters.

Whitespace and newlines are ignored, so the hex data can be easily formatted. The number of hex characters must be a multiple of 2.

Adjacent strings are concatenated with the operator, or by simple juxtaposition:

```
"hellou" ~ "world" ~ "\n" // forms the string
// 'h','e','l','l','o',' ',
// 'w','o','r','l','d',linefeed
```

The following are all equivalent:

```
"ab" "c"
r"ab" r"c"
r"a" "bc"
"a" ~ "b" ~ "c"
```

The optional *StringPostfix* character gives a specific type to the string, rather than it being inferred from the context. This is useful when the type cannot be unambiguously inferred, such as when over-

loading based on string type. The types corresponding to the postfix characters are:

Postfix	Type	Aka
c w	<pre>immutable(char)[] immutable(wchar)[] immutable(dchar)[]</pre>	string wstring dstring

```
"hello"c // string
"hello"w // wstring
"hello"d // dstring
```

The string literals are assembled as UTF-8 char arrays, and the postfix is applied to convert to wchar or dchar as necessary as a final step.

String literals are read only. Writes to string literals cannot always be detected, but cause undefined behavior

Delimited Strings

Delimited strings use various forms of delimiters. The delimiter, whether a character or identifer, must immediately follow the "without any intervening whitespace. The terminating delimiter must immediately precede the closing" without any intervening

whitespace. A *nesting delimiter* nests, and is one of the following characters:

Delimiter	Matching Delimiter
[]
()
<	>
{	}

```
q"(foo(xxx))" // "foo(xxx)"
q"[foo{]" // "foo{"
```

If the delimiter is an identifier, the identifier must be immediately followed by a newline, and the matching delimiter is the same identifier starting at the beginning of the line:

```
writefln(q"EOS
This
is aumulti-line
heredocustring
EOS"
);
```

The newline following the opening identifier is not part of the string, but the last newline before the closing identifier is part of the string. The closing identifier must be placed on its own line at the leftmost column.

Otherwise, the matching delimiter is the same as the delimiter character:

Token Strings

Token strings open with the characters q{ and close with the token }. In between must be valid D tokens. The { and } tokens nest. The string is formed of all the characters between the opening and closing of the token string, including comments.

0.2.10 Character Literals

```
CharacterLiteral:

Integers can be specified in decimal, binary, octal, or hexadecimal.

Decimal integers are a sequence of decimal digits.

Binary integers are a sequence of binary digits preceded by a '0b'.

C-style octal integer notation was deemed too easy to mix up with decimal notation. The above is only fully supported in string literals. D still supports octal integer literals interpreted at compile time through the std.conv.octal template, as in octal!167.

Hexadecimal integers are a sequence of hexadecimal digits preceded by a '0x'.

Integers can have embedded '_' characters, which are ignored. The embedded '_' are useful for formatting long literals, such as using them as a thousands separator:

```
123_456  // 123456
1_2_3_4_5_6_  // 123456
```

Integers can be immediately followed by one 'L' or one of 'u' or 'U' or both. Note that there is no 'l' suffix.

The type of the integer is resolved as follows:

Literal Usual decimal notation 0 .. 2_147_483_647 2_147_483_648 .. 9_223_372_036_854_775_807 Explicit suffixes 0L .. 9_223_372_036_854_775_807L 0U .. 4_294_967_296U

OUL .. 18_446_744_073_709_551_615UL

0x1_0000_0000 .. 0x7FFF_FFFF_FFFF_FFFF

Hexadecimal notation with explicit suffixes
OxOL .. Ox7FFF_FFFF_FFFFL

LeadingDecimal:

DecimalInteger

O DecimalDigitsNoSingleUS

Floats can be in decimal or hexadecimal format. Hexadecimal floats are preceded with a $\mathbf{0x}$ and the exponent is a \mathbf{p} or \mathbf{P} followed by a decimal num-

ber serving as the exponent of 2.

Floating literals can have embedded '_' characters, which are ignored. The embedded '_' are useful for formatting long literals to make them more readable, such as using them as a thousands separator:

Floating literals with no suffix are of type double. Floats can be followed by one **f**, **F**, or **L** suffix. The **f** or **F** suffix means it is a float, and **L** means it is a real.

If a floating literal is followed by \mathbf{i} , then it is an *ireal* (imaginary) type.

Examples:

It is an error if the literal exceeds the range of the type. It is not an error if the literal is rounded to fit into the significant digits of the type.

Complex literals are not tokens, but are assembled from real and imaginary expressions during se-

```
mantic analysis:
```

```
4.5 + 6.2i // complex number (phased out)
```

0.2.13 Keywords

Keywords are reserved identifiers.

```

0.2.14 Special Tokens

These tokens are replaced with other tokens according to the following table:

Special Token	Replaced with
DATE	string literal of the date of com- pilation "mmm dd yyyy"
EOF	sets the scanner to the end of the file
TIME	string literal of the time of compilation "hh:mm:ss"
TIMESTAMP	string literal of the date and time of compilation "www mmm dd hh:mm:ss yyyy"
VENDOR	Compiler vendor string, such as "Digital Mars D"
VERSION	Compiler version as an integer, such as 2001

0.2.15 Special Token Sequences

SpecialTokenSequence:

```
# line IntegerLiteral EndOfLine
# line IntegerLiteral Filespec EndOfLine
```

Filespec:

" Characters "

Special token sequences are processed by the lexical analyzer, may appear between any other tokens, and do not affect the syntax parsing.

There is currently only one special token sequence, #line.

This sets the source line number to IntegerLiteral, and optionally the source file name to Filespec, beginning with the next line of source text. The source file and line number is used for printing error messages and for mapping generated code back to the source for the symbolic debugging output.

For example:

```
int #line 6 "foo\bar"
x; // this is now line 6 of file foo\bar
```

Note that the backslash character is not treated specially inside *Filespec* strings.
